

School Lunch Quality and Academic Performance

Michael L. Anderson, Justin Gallagher, and Elizabeth Ramirez Ritchie*

August 8, 2017

Abstract

Improving the nutritional content of public school meals is a topic of intense policy interest. A main motivation is the health of school children, and, in particular, the rising childhood obesity rate. Medical and nutrition literature has long argued that a healthy diet can have a second important impact: improved cognitive function. In this paper, we test whether offering healthier lunches affects student achievement as measured by test scores. Our sample includes all California (CA) public schools over a five-year period. We estimate difference-in-difference style regressions using variation that takes advantage of frequent lunch-vendor contract turnover. Students at schools that contract with a healthy school-lunch vendor score higher on CA state achievement tests. We do not find any evidence that healthier school lunches lead to a decrease in obesity rates. The test score gains, while modest in magnitude, come at very low cost.

The authors would like to thank Janet Currie, Peter Hinrichs, Caroline Hoxby, Scott Imberman, Aaron Sojourner, and Mary Zaki for helpful comments on this project, as well as seminar participants at the Agricultural and Applied Economics Association annual conference and the NBER Education and Childrens' Program meetings. The authors also thank Jacqueline Blair, Paul Fisher, Anthony Gatti, Sarah Mattson, Jonathon Mobley, and Aaron Weisberg for outstanding research assistance. A special thanks to Grace Chan and Pat Crawford at the Nutrition Policy Institute for their analysis of the nutritional content of the lunches offered by the school lunch vendors. This work was supported by the Giannini Foundation of Agricultural Economics and the USDA National Institute of Food and Agriculture, Hatch Project 233535.

1 Introduction

Improving the nutritional content of public school meals in the United States (US) is a topic of intense policy interest (Confessore 2014). A primary motivation underlying these nutritional improvements is to increase student health and reduce childhood obesity rates. A question of comparable import, however, is whether healthier meals affect student achievement. Recent research demonstrates that the provision of subsidized school meals can significantly increase school test scores (Figlio and Winicki 2005; Dotter 2014; Imberman and Kugler 2014; Frisvold 2015), but to date little evidence exists on how the *quality* of school meals affects student achievement. This question is particularly important in light of recent arguments by policymakers that improved nutritional standards for school meals are ineffective or counterproductive (Green and Davis 2017).

To determine whether the quality of school meals affects student achievement, we exploit longitudinal variation in California school districts' meal vendors and estimate difference-in-differences type regressions. We combine two principal data sets from the California Department of Education, one covering breakfast and lunch vendors at the school level and the other containing school-by-grade-level standardized test results. Our five-year panel dataset includes all CA public elementary, middle, and high schools with non-missing state test score data (about 9,700 schools). For each California public school, we observe whether the district in which the school is located had an outside contract with a meal provider for the school year, and, if so, the name of the provider and the type of contract. The vast majority of schools provide meals

using “in-house” staff, but a significant and growing fraction (approximately 12%) contract with outside vendors to provide meals. Crucially for our research design, there is substantial turnover in vendors at the school-district level during our sample period. Among schools in our panel that contract with an outside vendor, 62% switch between preparing meals in-house and contracting with a vendor.

A central obstacle in estimating the effects of healthy meal vendors on academic performance is accurate measurement of nutritional quality. We measure the nutritional quality of vendor school lunches using a modified version of the Healthy Eating Index (HEI). The HEI is a continuous score ranging from 0 to 100 that uses a well-established food-component analysis to determine how well food offerings (or diets) match the Dietary Guidelines for Americans (e.g., Guenther et al. 2013b). HEI is the measure of diet quality preferred by the United States Department of Agriculture (USDA) (USDA 2006) and has previously been used by researchers to evaluate menus at fast-food restaurants and child-care centers. We contracted with trained nutritionists at the Nutrition Policy Institute to calculate vendor HEI scores for this project.¹ Using their scores, we classify a vendor as healthy if its HEI score is above the median score among all vendors in our sample and as standard otherwise.

We find that contracting with a healthy meal vendor increases test scores by 0.03 to 0.04 standard deviations relative to in-school meal provision, after conditioning on school-by-grade and year fixed effects. This result is highly significant and robust to the inclusion or exclusion of our time-varying covariates,

¹http://npi.ucanr.edu/About_Us/

including demographic characteristics of the students, school district expenditures, student-teacher ratios, and changes in school leadership. The point estimates are also very similar whether they are estimated on the baseline sample of all CA schools or samples restricted to those schools that ever contract with an outside vendor. When estimating effects separately for economically disadvantaged and non-disadvantaged students, we find modest evidence that the effect of contracting with a healthy vendor is larger for economically disadvantaged students than for non-disadvantaged students. There is no evidence that contracting with a standard vendor affects test scores.

We conduct various tests to support the identifying assumption that the exact timing of vendor contracts is uncorrelated with other time-varying factors that may affect test scores. The frequent turnover in lunch vendor contracts makes it less likely that an unobservable factor could explain our test score results, as this factor would need to be highly correlated with the timing of new contracts for healthy lunch vendors but not standard vendors. Event study specifications and “placebo” tests where the treatment activates one year prior to the actual treatment year provide evidence that test scores are not correlated with *future* changes in vendors (i.e., there are no differential trends preceding a new vendor contract). We also find that changes in observable characteristics of schools are uncorrelated with new vendor contracts. In particular, there is no evidence that changes in test scores predict when a school will contract with a vendor.

Introducing healthier school lunches does not appear to change the *number* of school lunches sold, which supports our interpretation that the change in

test scores is due to the quality rather than the quantity of the food. At the same time, this result helps to alleviate concerns that offering healthier lunches could lead to lower consumption by economically disadvantaged students who qualify for free or reduced price school lunch. Similarly, we do not find that healthier school lunches lead to a decrease in obesity rates. One explanation for the null effect on the percent of overweight students is that all school lunches – healthy vendor, standard vendor, and in-house – are subject to the same USDA calorie requirements.

Although our estimated test score effects are modest on an absolute scale, they are highly cost-effective for a human capital investment. We calculate a plausible upper bound on the cost of contracting with a healthy lunch provider, relative to in-house meal preparation, of approximately \$123 (2013 \$) per test-taker per school year. Using our preferred estimate of 0.031 standard deviations, this result implies that it costs (at most) \$40 per year to raise a student’s test score by 0.01 standard deviations. Despite assuming high costs, the cost effectiveness of contracting with healthy vendors matches the most cost-effective policies highlighted by Jacob and Rockoff [2011], and it compares very favorably when measured against interventions that achieve larger absolute effects, such as the Tennessee STAR class-size reduction experiment (Krueger 1999).

2 Background and Data

2.1 Related Literature

There is a large medical and nutrition literature examining the link between diet and cognitive development, and between diet and cognitive function (e.g., Bryan et al. 2004; Sorhaindo and Feinstein 2006; Gomez-Pinilla 2008; Nandi et al. 2015). Sorhaindo and Feinstein [2006] review existing research on the link between child nutrition and academic achievement and highlight how nutrition can affect learning through three channels: physical development (e.g., sight), cognition (e.g., concentration, memory), and behavior (e.g., hyperactivity). Gomez-Pinilla [2008] outlines some of the biological mechanisms regarding how both an increase in calories and an improvement in diet quality and nutrient composition can affect cognition. For example, “diets that are high in saturated fat are becoming notorious for reducing molecular substrates that support cognitive processing and increasing the risk of neurological dysfunction in both humans and animals” (Gomez-Pinilla 2008, p. 569). Most of the direct evidence on how nutrition affects academic achievement among school-age children comes from studies of children in developing countries (Alderman et al. 2007 and Glewwe and Miguel 2008 provide reviews).

A number of recent studies have estimated the effect of increased availability of either breakfast or lunch under the NSLP on student test scores in the US. Many of these studies find evidence that improved access to breakfast or lunch increased test scores (e.g., Figlio and Winicki 2005; Dotter 2014; Imberman and Kugler 2014; Frisvold 2015), while others find no effect (e.g.,

Leos-Urbel et al. 2013; Schanzenbach and Zaki 2014). In all of these studies, the main hypothesized channel between the increased take-up of the school breakfast and lunch programs and test scores is an increase in calories consumed. The NSLP may also have broadly increased educational attainment by inducing children to attend school (Hinrichs 2010).

Our paper focuses on the nutritional quality of the calories provided. We are aware of just one other study that estimates the effect of food quality on academic test scores. Belot and James [2011] estimate the effect of introducing a new, healthier school lunch menu in 80 schools during the same academic year in one borough in London, as compared to schools in a neighboring borough. The authors estimate a positive effect on test scores for elementary school students, but find that the effect is larger for higher socioeconomic students who do not qualify for reduced price or free school lunch.

Relative to Belot and James [2011], we provide evidence from a much larger sample that includes all CA public schools (roughly 9,700 schools), of which 1,188 contract with an outside lunch provider. Our estimation approach uses within-grade and school variation in the introduction *and* removal of healthy and standard lunch providers that occurs in each of the five years of our panel. Thus, we can account for constant unobserved grade-by-school effects. Further, the staggered timing of the lunch contracts allows us to flexibly control for unobserved (calendar) time effects, and to conduct a series of robustness checks regarding the exogeneity of the timing of the contracts. Finally, like Belot and James [2011], we estimate the effect of healthier school lunches on the number of lunches served; however, unlike Belot and James [2011], we are also able to

test whether healthier lunch provision changes obesity rates.

2.2 Data Sources

The data for this project come from the State of California Department of Education. We use information on school-level breakfast and lunch vendors, and school-by-grade-level standardized test results. We describe each type of information in detail below.

2.2.1 Vendor Data

The vendor meal contract information is provided by the California Department of Education for the school years 2008-2009 to 2012-2013.² All food vendor contracts with public (K-12) schools in California must be approved by the CA Department of Education. The CA Department of Education retains a list of the schools that contract with an outside meal provider for each school year, the name of the provider, and the type of contract. A total of 143 school districts covering 1,188 schools contracted with a total of 45 different vendors during our sample period. We merged the food vendor contract information with the list of all public schools (including charter schools) operating in CA during this time period to create our estimation panel. Overall, 12% of CA public schools contracted for at least one academic year with an outside company to provide school lunch.

²The data were received as part of an official information request. We thank Rochelle Crossen for her assistance in facilitating the request and in interpreting the data. Contract information for school years prior to 2008-2009 was not retained when the CA Department of Education switched computer database systems.

Appendix Table A1 lists the 45 vendors and the percent of students served by each vendor (conditional on being served by any vendor). For each vendor, we first calculate the number of (STAR) test-takers in districts that are being served by that vendor. This vendor-level total is then divided by the total number of test-takers being served by outside vendors. A single vendor serves just over 50% of the students. Altogether, the vendors with the ten largest student test-taker market shares serve 97.5% of CA students enrolled in schools that contract with outside school lunch providers.

Nearly all of the contracts (94%) are signed in the summer and cover the entire academic school year.³ The CA Department of Education classifies all food provision contracts as one of four types: Vendor, Food Service Management Company (FSMC), Food Service Consulting Company (FSCC), and School Food Authority (SFA). A Vendor contract is when a school contracts with a private company to provide meals, but school employees (i.e., cafeteria staff) still handle and serve the food, including any additional prepping and cooking. In a FSMC contract, a private company prepares the meals and assists in staffing the school with cafeteria workers who serve the meals. In a FSCC contract, a private company provides “consulting services” on meal preparation and staffing, but does not provide any personnel for the jobs. SFA contracts usually denote that one public school district contracts with another district for meal provision. SFA contracts are unusual and account for just 1% of the contract-grade years. We do not distinguish between the four types of

³A small number of contracts cover less than the complete school year. These contracts correspond to the calendar year and thus cover only a fraction of the school year (August-December or January-June). Estimation results are insensitive to the inclusion of these contracts in our sample.

contracts in the main analysis of the paper and, unless otherwise specified, we refer to all such companies as “vendors.”

Detailed vendor contract information is available for a subset of the contracts. Contract details include meals provided (either lunch or both breakfast and lunch), the dollar value of the contract, the number of other contract bidders (if any), the names of the companies which bid for the contract and were not selected, the dollar value of losing contracts, and the method by which the contract bids were solicited (i.e., sealed bid or negotiation). In the main analysis, we do not distinguish between vendors that provide both lunch and breakfast and those that provide only lunch, as this information is only available for a minority of the contracts.⁴ We use the contract bid information to help construct counterfactual estimates for the cost to improve state test scores by contracting with healthy lunch providers.

The nutritional quality of the vendor school lunches is assessed using the Healthy Eating Index (HEI). The HEI is the US Department of Agriculture’s (USDA) preferred measure of diet quality (USDA 2006), and the USDA uses it to “examine relationships between diet and health-related outcomes, and to assess the quality of food assistance packages, menus, and the US food supply” (USDA 2016). HEI has been used by researchers to assess both individual diets (e.g., Volpe and Okrent 2012; Guenther et al. 2013a) and the diets of

⁴The contract details are not available for all contracts for two reasons. First, school districts are only required to provide contract details to the state for the first year of a new contract. A contract can be renewed up to four times without having to issue a new contract. Second, school officials enter the contract information via a software program that electronically stores the data in the CA Department of Education database. In practice, many of the data fields are missing for most of the new contracts. This is because, until recently, the CA Department of Education didn’t have the staff to review the contract price and bid data entered into the system.

subpopulations (e.g., Hurley et al. 2009; Manios et al. 2009), as well as food offerings at fast food restaurants (e.g., Reedy et al. 2010) and child-care centers (e.g., Erinoshio et al. 2013). The HEI scores range from 0 to 100, with higher scores representing healthier diets (or food offerings). Scores are calculated via a food component analysis done on a per calorie basis (Guenther et al. 2013b).

We contracted with nutritionists at the Nutrition Policy Institute to calculate vendor HEI scores using sample school lunch menus. Over the course of one year they collected detailed vendor data, refined the HEI score methodology, and computed the scores. Appendix A1 provides details of the HEI score calculations, and a link to the Nutrition Policy Institute report includes examples of menus used as part of the analysis.⁵ Menu information was not available for all of the vendors, and as a result some vendors were not assigned HEI scores. Appendix Table A1 shows that this is mostly the case for vendors that contract infrequently with schools. Overall, HEI scores are calculated for 87.3% of student test-takers served under vendor contracts. The median vendor HEI score in our sample is 59.9. This median vendor score is similar to the average HEI score, 63.8, for the US population age two and older (USDA 2006, p. 21). We define a vendor as healthy if it has a vendor HEI score above the median vendor score. Healthy vendors are more likely to provide salad bars and sufficient amounts of fruits, vegetables, whole grains, dairy, and

⁵In preparing their analysis, the nutritionists assumed that all vendors met the baseline USDA requirements, as they are obligated by law to do so. They also assumed that the average meal contains 650 calories, and they matched food items to foods available in the USDA food database. The classification of vendors as healthy or standard was not sensitive to any of these choices.

seafood or plant proteins. They serve fewer processed meats, fast-food items, fried potatoes, chocolate milk, sweets, and chips or other salty snacks, and their meals tend to contain less refined grains, sodium, and “empty calories.”⁶ Alternative classifications (e.g., coding any vendor with an HEI score above the mean vendor score as healthy) generate similar results. While no classification system is perfect, it is notable that misclassifying healthy vendors as standard, and vice versa, will only attenuate our estimates.

2.2.2 Academic Test Data and Covariates

To measure academic achievement, we use California’s Standardized Testing and Reporting (STAR) test data. The STAR test is administered to all students in grades 2 through 11 each spring, toward the end of the academic year. The publicly available test scores are aggregated at the grade-by-school level. We use test score data from 1998 through 2013. Beginning with the 2013-14 school year, STAR testing was replaced with the California Assessment of Student Performance and Progress test.

The STAR test includes four core subject area tests (English/Language Arts, Mathematics, History/Social Sciences, and Science) and a set of end-of-course examinations (e.g., Algebra II, Biology). We create a composite test score each year for each school-grade by calculating the average test score across all of the STAR subjects and the end-of-course tests taken by students in a particular grade in each school. We use the standard deviation of each

⁶Fast-food items include chicken nuggets, pizza or pizza pockets, hamburgers, fried chicken, nachos, hot dogs, and corn dogs. “Empty calories” are those that come from solid fats, alcohol, and added sugars.

test (which differs by grade and year of test) to standardize each subject and end-of-course test score before combining the scores into a single composite score.⁷

Average test scores are also available separately for students who qualify for reduced price and/or free school lunch under the NSLP. A student is eligible for a free school lunch if his family’s income is less than 130% of the poverty level, and a reduced price lunch if her family’s income is between 130% and 185% of the poverty level.⁸ The CA Department of Education refers to these students, as well as students with parents who do not have high school diplomas, as “economically disadvantaged” (California Department of Education 2011, p. 48). Students eligible for the reduced price or free lunches are more likely to eat the lunch offered at the school, for two reasons: the price is lower for them than it is for ineligible students, and eligible students are less likely to have other lunch options. Furthermore, the nutritional quality of their home-provided meals may be lower than that of the average student. Thus, we hypothesize that the academic benefit of having healthier school lunches may be larger for these students.

Finally, district-level demographic and socioeconomic information is avail-

⁷The qualitative results are robust to using only core test results, or in using just the English/Language Arts exam (which is the only exam taken by students in each grade). However, the point estimates are lower in specifications that only use test results from the English/Language Arts exam. This is consistent with other recent studies that separately measure the effect of access to school breakfast on test scores in different subjects (e.g., Dotter 2014; Imberman and Kugler 2014).

⁸Note that eligibility does not imply participation. Dahl and Scholz [2011] estimate that 28% to 49% of eligible children participate in free or reduced-price school breakfasts, and 63% to 73% of eligible children participate in free or reduced-price school lunches. Even estimates for disadvantaged children thus represent “intent to treat” effects rather than full treatment effects.

able from the California Department of Education, including enrollment by race, enrollment in English learner programs (i.e., English as a second language), and the number of enrolled students who are economically disadvantaged, as defined by eligibility for free or reduced price lunches. We use this information to control for time-varying differences within schools in our main econometric model.

3 Empirical Specification

Our main empirical specification is a panel regression model.

$$y_{gst} = \beta_0 + \delta_H \text{Healthy}_{st} + \delta_S \text{Standard}_{st} + X_{st} \beta + \lambda_{gs} + \gamma_t + \epsilon_{gst} \quad (1)$$

The dependent variable y_{gst} is the mean STAR test score across all tests for grade g in school s in year t . The dependent variable is measured in STAR test standard deviation units.

Our independent variables of interest are indicators for whether a student test-taker is exposed to a standard or healthy outside lunch provider. Recall that a provider is classified as healthy if its HEI score is above the median score among providers. The variable Healthy_{st} equals one if school s contracts with a healthy outside lunch provider in year t and zero otherwise. The variable Standard_{st} equals one if school s contracts with a standard outside lunch provider in year t and zero otherwise. The “omitted” category for our treatment indicators corresponds to the case in which the school does not contract with an outside lunch provider. In this case the school’s employees (i.e.,

cafeteria workers) both prepare and serve the lunches.

The model includes school-by-grade (λ_{gs}) and year (γ_t) fixed effects. The school-by-grade fixed effects control for any characteristics in a given grade and school that are stable throughout the five-year estimation period (e.g., school catchment area characteristics, school infrastructure, STAR test differences by grade, or school staffing levels and leadership). Year fixed effects control for common state-wide factors such as state economic conditions and differences in the STAR test that vary by year throughout the panel. All specifications also include an indicator for contracting with a meal vendor of unknown HEI quality, $Unscored_{st}$. This category accounts for 13% of vendors on a test-taker weighted basis. In our regressions the coefficient on $Unscored_{st}$ lies, as we would expect, between the coefficients on $Healthy_{st}$ and $Standard_{st}$ and sometimes achieves statistical significance. However, we cannot interpret it since we do not know the fraction of unscored vendors that are healthy, so we treat it as an additional control.

Most specifications of the model also include X_{st} , a vector of district-level control variables that vary over time. These control variables include the racial composition of students in the district to which school s belongs, the proportion of students in English learner programs, and the proportion of economically disadvantaged students. Because the decision to contract with a lunch vendor (whether healthy or standard) almost always occurs at the district level, as opposed to the individual school level, it is sufficient to control for district-level covariates that may be correlated with this decision.⁹

⁹We also experimented with controlling for similar school-level covariates that we constructed directly from the STAR data. Controlling for these covariates at the school level

Contract typically cover all schools in a district, so we estimate Equation (1) with standard errors clustered at the school-district level. Our preferred specification uses the number of test-takers for each grade-school-year observation as weights in the regression. Weighting by the number of test-takers allows us to recover the relationship between the type of school lunch served and academic performance as measured by the STAR test for the average student, rather than the average school.

The identifying assumption is that, after controlling for time-invariant school-by-grade factors, common state factors, and the vector of time-varying, school-level characteristics, a school’s decision to contract with an outside vendor for school lunch provision is uncorrelated with other school-specific, time-varying factors that affect student test performance. If this is true, then we can interpret the estimate for δ_H (and δ_S) as the causal effect of contracting with a healthy (or standard) school lunch provider on student learning, as measured by performance on the STAR test.

4 Results

4.1 Vendor Choice and Test-Taker Characteristics

Appendix Table A2 shows mean test-taker socioeconomic and racial characteristics for school districts in two different samples: the *All School* sample and the *Contract School* sample. The All School sample includes all school

has little impact on the coefficient estimates, but it results in many dropped observations because of frequent missing demographic information in the STAR data.

districts in the state of California. The Contract School sample is limited to the subset of districts that had a school lunch vendor contract for at least one year in our five-year panel. The means for each test-taker characteristic are calculated by first taking the five-year (2009-2013) district-level mean. In the All School sample, the average district mean is then calculated separately for districts that contract with a vendor (Column 1) and do not contract with a vendor (Column 2) during our panel (2009-2013). Column (3) calculates the difference in means and reports the standard error for this difference (in parentheses). The means are statistically different from each other at the 5% level for five of the six characteristics. For example, districts that contract with a vendor during our sample period tend to have fewer economically disadvantaged students and a higher proportion of Asian students.

Appendix Table A2 also shows that, even among districts that contracted with a vendor at some time, those districts that contracted with a healthy vendor have different student characteristics (on average) than those districts that contracted with a standard vendor. These differences in test-taker characteristics in the two samples affect the generalizability of any association between test scores and vendor quality. Nevertheless, the differences in average characteristics between test-takers do not violate the identification assumptions of Equation (1).

Table 1 shows how *changes* in the test-taker characteristics correlate with the timing of a vendor contract. We cannot interpret an observed correlation between vendor adoption and test score changes as a causal effect if changes in test-taker characteristics at a school can predict when a school contracts with

an outside vendor. Table 1 displays the coefficient estimates from 12 different regressions using a version of Equation (1). In each of the first five columns, we use a different test-taker characteristic as the dependent variable in place of test scores. In the last column, we use the fitted values from a regression of test scores on all five test-taker characteristics (and year and school-by-grade fixed effects) as the dependent variable. These fitted values summarize all of the test-taker characteristics, weighting each characteristic in relation to its correlation with test scores. All regressions in Table 1 include school-by-grade fixed effects and thus test whether within-school-by-grade changes in student characteristics correlate with the time at which a school adopted an outside lunch provider.

Panel A of Table 1 estimates models using the All School sample,¹⁰ while Panel B uses the Contract School sample.¹¹ The point estimates are small in magnitude and precisely estimated. None of the estimated coefficients are statistically significant at conventional levels. The estimate in the last column of Panel A reveals that adoption of a healthy vendor correlates with a statistically insignificant 0.005 standard deviation increase in predicted test scores. The estimate for adoption of a standard vendor is also statistically insignificant. We interpret these results as initial evidence that changes in test-taker characteristics are uncorrelated with the timing of when a school contracts with a lunch provider. Sections 4.3 and 4.4 consider additional tests of the validity of our identifying assumption.

¹⁰This includes all elementary, middle, and high schools in California that report STAR scores.

¹¹This comprises all schools located in districts that had a school lunch vendor contract for at least one year in our five year panel.

4.2 Vendor Choice and Test Scores

Table 2 shows estimation results for the effect of vendor quality on STAR scores. The first three columns estimate versions of Equation (1) on the All School sample, while the last three columns use the Contract School sample. Column (1) estimates the effect of contracting with a standard or healthy lunch vendor on test scores and includes school and year fixed effects as controls. Column (2) adds school-by-grade fixed effects, while Column (3) adds the vector of student test-taker characteristics. The point estimate of the effect of having a healthy vendor on test scores, relative to no outside vendor, is 0.031 standard deviations and is highly significant at the 0.1% level in each of the three specifications. Moreover, we are able to reject the null hypothesis that the coefficients for the healthy and standard vendors are equal at the 10% level for each specification. The standard vendor coefficient is an order of magnitude smaller and not statistically different from zero in any specification.

The estimates for a healthy vendor from the Contract School sample are also statistically significant at the 0.1% level and are similar in magnitude to those estimated with the All School sample (ranging from 0.033 to 0.037). The estimates for the standard vendor are again an order of magnitude smaller and not statistically significant.¹²

The fact that we observe very similar point estimates for the vendor coef-

¹²Our results are also qualitatively similar if we estimate Equation (1) without using student enrollment weights. These results can be found in Appendix Table A3. The point estimate for those vendors with an unknown HEI score (not shown in table) are positive, range between 0.01 and 0.02 standard deviations, and are statistically significant in some specifications. This is not too surprising as we expect these vendors to be a mix of standard and healthy vendors.

ficients in Columns (2) and (3) (and Columns (5) and (6)) is consistent with the conclusion from Table 1. If student characteristics were important in predicting when a school contracts with an outside vendor, then the coefficients in Table 1 would be statistically significant and the vendor estimates in Table 2 would likely be sensitive to the inclusion or exclusion of these controls.

Table 3 investigates whether the effect of contracting with a lunch provider on STAR scores is different for economically disadvantaged and economically advantaged students. Recall that economically disadvantaged students are defined by the CA Department of Education as those students who qualify for reduced price and/or free school lunch under the NSLP based on family income. We expect that disadvantaged students would be more likely to eat a school lunch than their classmates who do not qualify for reduced price or free school lunch. Thus, we hypothesize that the effect on test scores of healthy school lunch vendors should be somewhat greater for disadvantaged students than for students who do not qualify for reduced price or free school lunch. Table 3 shows evidence consistent with this hypothesis.

Table 3 again considers both the All School and Contract School samples, but limits the samples to those schools which report separate average STAR scores for both economically advantaged and economically disadvantaged students.¹³ Column (1) of Table 3 estimates the effect of contracting with a lunch vendor on the average test score for economically disadvantaged students. Column (2) estimates the effect on the average test scores for eco-

¹³Due to privacy restrictions, the CA Department of Education releases the average test score (for a school-grade-year-subgroup) only if there are at least 10 students of the particular socioeconomic group who take the test. There is a 40% reduction in the size of the sample due to these sample restrictions.

nominally advantaged students, while Column (3) estimates the effect for all students. The point estimates for contracting with a healthy vendor are about 40 to 50% larger for the disadvantaged students in both samples. In the All School sample the estimated coefficients are 0.035 and 0.025 respectively, while in the Contract School sample they are 0.046 and 0.030 respectively. There is again no evidence that a standard vendor has a statistically significant effect on test scores relative to having meals completely prepared by school staff.

4.3 Robustness Checks

Table 1 presents initial evidence that changes in test-taker characteristics are uncorrelated with the timing of when a school contracts with a lunch provider. In this section, we further test the validity of our identifying assumption that a school’s decision to contract with an outside vendor for school lunch provision is uncorrelated with other school-specific, time-varying factors that affect student test performance.

Equation (2) is an event-study model that tests whether there is a correlation between test scores and contracting with a vendor in years before the vendor contract begins and in each year of the contract.

$$y_{gst} = \beta_0 + \sum_{\tau=-4}^4 \delta_H^\tau \text{Healthy}_{st}^\tau + \sum_{\tau=-4}^4 \delta_S^\tau \text{Standard}_{st}^\tau + X_{st}\beta + \lambda_{gs} + \gamma_t + \epsilon_{gst} \quad (2)$$

Equation (2) is identical to our main estimating equation, except that we replace the single indicator variables for whether a school contracted with a

vendor ($Healthy_{st}$ and $Standard_{st}$) with a set of indicators ($Healthy_{st}^\tau$ and $Standard_{st}^\tau$). Indicators with $\tau < 0$ are indicators for the years before a contract with a healthy (or standard) vendor begins. Indicators with $\tau > 0$ are indicators for the consecutive years after a contract with a healthy (or standard) vendor begins, while the contract is still in effect.¹⁴ The indicator variables for a year before a contract are normalized to zero when we estimate Equation (2). Thus, the estimated coefficients δ_H^τ and δ_S^τ are interpreted as the change in test scores for students in grade g , school s , and year t relative to the year before a contract.

Figure 1 plots the estimated healthy vendor event time coefficients and the 95% confidence intervals for the All School sample. The x -axis measures event time years (i.e., τ), and the y -axis measures test scores for all test takers.¹⁵ In a healthy vendor contract year, there is an increase in test scores of 0.030 standard deviations relative to the year before a contract.¹⁶ There is no evidence that increases in test scores precede contracting with a vendor, nor is there evidence of an upward pre-trend in test scores. Similarly, none of the estimated coefficients in the years after a contract begins are significantly different than the $\tau = 0$ coefficient, suggesting that there are not delayed impacts that take several years to materialize. Figure 2 plots analogous event time coefficients

¹⁴For example, $Healthy_{st}^{-3}$ equals unity if a school contracted with a healthy vendor three years later (and zero otherwise), and $Healthy_{st}^3$ equals unity if a school contracted with a healthy vendor three years earlier and has continued to contract with a healthy vendor each year since (and zero otherwise).

¹⁵The post-event coefficients in the figure compare the counterfactual of a contract that remains in effect indefinitely to one in which there is no contract; e.g., at $\tau = 2$ we plot $\delta_H^0 + \delta_H^2$. This aligns the figure with a standard event study figure in which the policy always remains in effect following the event.

¹⁶As a comparison, the estimate of the effect on test scores for the year of a healthy vendor contract from Equation (1) on the same sample is 0.031 (Column (3) of Table 2).

for standard vendors. None of the standard vendor coefficients, either before or after the contract’s start date, are statistically significant.¹⁷

There are two caveats to the analysis in Figures 1 and 2. First, the event study coefficients toward the ends of our panel are imprecisely estimated because there are fewer observations available to identify these coefficients.¹⁸ We address this concern by also estimating a model that pools the event time coefficients. Second, we do not know whether a school contracted with a vendor in the years before our five-year panel begins. This could attenuate our estimates if there are delayed impacts in the test score effect that appear several years after contracts begin, because the model would incorrectly assume zero treatment effect in the pre-vendor years.¹⁹ We conclude that this is unlikely to be a concern, however, because our event study finds no evidence of delayed impacts.

Table 4 presents the estimation results of six additional specifications that further test our identifying assumptions and the robustness of our main test score results. All six specifications can be interpreted relative to our baseline model in Table 2, Column (3). Column (1) presents results for a regression

¹⁷We also estimate a model, similar in spirit to Equation (2), that regresses an indicator for when a contract starts on lagged test scores. We run the model separately for healthy, standard, and unknown contracts, and include four lagged test score variables. This model tests whether changes in test scores predict vendor adoption, and it uses the full sample because test scores are available in years before 2008-2009 (the first year of our vendor data). In this model none of the lagged test score coefficients are statistically significant.

¹⁸For example, the indicator for four years before a vendor contract can equal one only if a school contracted with a vendor in the last year of our panel. By contrast, an indicator for one year after a vendor contract ends could equal one for four of the five years in our panel.

¹⁹For example, Gallagher [2014] examines the effect on the take-up of flood insurance after a community is flooded, using a model similar to Equation (2). He shows that the estimate for flood insurance take-up in the year of a flood is about 20% lower if the model fails to control for the lagged effect of a flood that occurred before the panel period.

that estimates separate effects for vendors whose contracts run for the full academic year and those that end earlier. Students take STAR tests in April, and while most vendor contracts run through June, a small number end between November and February. If test scores increase solely because students have access to better food on test days, then we should expect no effect for contracts that end before the test date. The results in Column (1), however, reveal large and statistically significant effects for vendors whose contracts end several months before the test date. The coefficient for these contracts is larger than the coefficient for other healthy vendor contracts, but the difference is not statistically significant. These results suggest that healthy vendors may improve learning rather than simply improving performance on test days.

Columns (2) and (3) of Table 4 alter how we define a healthy vendor. Column (2) uses a second, slightly different, scoring method where the HEI score is supplemented by awarding additional points for healthy options that exceeded USDA requirements (e.g., salad bars) and subtracting points for unhealthy options (e.g., fast foods, certain processed foods, and high-sugar foods). The definition of a healthy vendor remains the same — one that receives a score above the median. The coefficient estimates for both the healthy and standard vendors are similar to those in the baseline model.

Column (3) uses the same HEI scores as the baseline model, but considers the scores as a continuous variable. Specifically, the model is adjusted to include an indicator variable for having a vendor with a known HEI score (rather than separate healthy and standard indicators) and an HEI score variable (divided by 100). The HEI score variable is zero if the school does not contract

with a vendor that has a known HEI score, and we recenter the HEI score so that zero corresponds to the average HEI score for a standard vendor in our sample (56.0). With this recentering we may interpret the indicator for a vendor having a known HEI score as the average effect of a standard vendor. The estimated coefficient for the HEI score variable is positive and statistically significant. The difference in average HEI scores between healthy and standard vendors is 17.5, so the point estimate implies that a healthy vendor increases test scores by approximately 0.027 standard deviations relative to no vendor, or 0.022 standard deviations relative to a standard vendor. The highest and lowest rated vendors by HEI score are Revolution Foods (92.3) and Kid Chow (26.8). The model implies that the effects of contracting with each vendor on test scores are 0.050 and -0.032 , respectively.

Column (4) reports a specification in which we aggregate the data to the district-by-year level, since the variation in vendor quality occurs almost exclusively at the district level. The estimated marginal effect of a healthy vendor on test scores is similar to that from our baseline specification.²⁰

Column (5) of Table 4 considers a placebo test where we incorrectly consider the year before a vendor contract as the year of a contract (Currie et al. 2010). We define *healthy placebo* (*standard placebo*) as equal to one if the school contracts with a healthy (standard) vendor in the following year. The estimated coefficients for both vendor placebos are close to zero and not statistically different from zero after controlling for the actual vendor years. There

²⁰Note that the healthy and standard vendor variables are weighted averages of the school-by-grade level exposure to the vendors in each year and thus take on values between 0 and 1. The average value for the healthy vendor variable (conditional on having at least one school in the district that contracted with a healthy vendor for the year) is 0.95

is no evidence that test scores begin to rise in the year before a school contracts with a vendor.²¹

We also consider a second event-study style placebo test where we separately estimate the correlation between test scores and panel years without a vendor. The econometric model is similar to Equation (2), except that we define $\tau > 0$ as years after *ending* a contract. In this specification, the $\tau = 0$ event study coefficient, $\delta_H^{\tau=0}$, is averaged across all years with a healthy vendor. If our model is correctly specified, we would only expect to measure a correlation between test scores and a vendor contract for healthy vendors when $\tau = 0$.²² Appendix Figure A1 shows that this is indeed the case. All of the estimates for the standard vendor coefficients are economically small and statistically insignificant. The same is true for the healthy vendor coefficients, except during years when a school contracts with a vendor ($\tau = 0$); in those years we estimate a statistically significant effect of 0.030.

Column (6) considers the sub-sample of schools from the Contract Sample that ever contracted with a standard vendor. As in the contract sample, this sample excludes schools that never had an outside vendor and further restricts the sample by excluding schools whose only outside vendors have been categorized as healthy (or unknown quality). Notably, the healthy vendor coefficient is estimated on a smaller sample of schools, only a fraction of which ever contract with both a standard and a healthy vendor. Nevertheless, the

²¹This specification also includes unknown vendor placebos. The estimated placebo coefficients are also close to zero and not statistically significant in a specification that does not condition on the actual vendor years.

²²One potential exception is that we might expect the estimates for the healthy vendor to be positive when $\tau > 0$ if there is a “carry-over” effect on learning in years after the cancellation of a healthy vendor contract.

point estimate, while not statistically significant, is very similar to the estimate from the larger All School and Contract School samples. The similarity in the coefficient estimates across the three samples provides further evidence that our results are not driven by differential trends in test scores among the schools that contract with a healthy vendor.

4.4 Alternative Explanations

Table 5 tests several alternative explanations for the observed relationship between healthier school lunches and test scores. One concern that our robustness checks above do not necessarily test is that changes in vendor contracts may coincide with changes in school leadership or district-wide investments. To address this concern we test whether changes in school-district expenditures, student-to-teacher ratios, the percentage of students enrolled in charter schools, or school leadership can explain our results. To conduct these tests we merge additional data sources with our baseline panel. The new data sources, however, do not include information for all schools. Table 5 thus reports our vendor coefficient estimates when we restrict the estimation samples to observations with non-missing expenditure, student-teacher ratio, superintendent, or charter school enrollment data, and then shows how the vendor coefficient estimates change when we control for each factor.

Columns (1) and (2) consider a sample with non-missing information for school expenditures and student-teacher ratios. The estimated coefficients for healthy and standard lunch providers in Column (2) are virtually identical to those without the expenditure and student-teacher controls in Column (1).

Neither the expenditure nor student-teacher coefficient is statistically significant, and in separate regressions we also find no statistically or economically significant relationship between either measure and healthy vendor adoption.²³

Columns (3) and (4) consider a sample with non-missing information on changes in district superintendents.²⁴ Column (4) includes an indicator equal to unity in years when there is a new superintendent. The estimated coefficient for the new superintendent variable is economically small and statistically insignificant, and the vendor point estimates are unaffected by whether we control for having a new superintendent.

Columns (5) and (6) estimate regressions on a sample of school districts with non-missing information on the percentage of students enrolled in charter schools. The model in Column (6) includes a variable for the fraction of students in the district enrolled in a charter school. School districts with a larger fraction of students enrolled in charter schools may have more flexibility to deviate from traditional school policies. Controlling for the fraction of charter school students, however, does not affect our vendor coefficient estimates.²⁵

²³The expenditure and student-teacher ratio data come from the CA Department of Education and are only available at the district level. We convert the expenditure data to thousands of dollars (2013 \$) per average daily student attendance. Results are similar if we separately control for expenditures and student-teacher ratio.

²⁴The CA Department of Education only retains information for current superintendents. We contacted each CA school district in our sample by email and phone between May and July 2017 to obtain historical information on whether there was a change of superintendent during our panel period. We successfully obtained information from 55% of the districts in our sample. Among these districts, 59% had at least one change of superintendent during our panel.

²⁵We also estimate our model baseline after first splitting our sample into two groups based on whether the school is a charter school. The estimated healthy vendor coefficient is also the same to three decimal places for both samples. The source of the charter school and population data is the CA Department of Education. 306 districts include at least one charter school during our panel. The average yearly percent of students enrolled in a charter school for a district during this time period is 7%.

5 Discussion

5.1 Student Health

Congress passed the Healthy, Hunger-Free Kids Act (HHFKA) in 2010 with the aim of increasing the minimum nutritional standards that school lunches must meet. For example, the number of mandated servings of fruits and vegetables increased, while at the same time restrictions were placed on the number of servings of French fries (USDA 2012a). A major goal of the law is to improve the health of school-age children via a reduction in obesity (USDA 2013).

Previous research has shown that the source of a student's school lunch can affect obesity rates. Schanzenbach [2009] provides evidence that public school lunches have contributed to increases in childhood obesity rates. Students who are more likely to consume public school lunches, rather than other options such as bringing a brown-bag lunch, gain more weight. Currie et al. [2010] estimate that less than one academic year of exposure to fast-food restaurants near schools increases obesity rates for 9th grade students by about 5%. Currie et al. [2010] and Cutler et al. [2003] both emphasize that large increases in obesity rates could occur from as few as 100 excess calories per day.

We use the same source of physical fitness information as Currie et al. [2010] to test whether exposure to healthier school lunch options decreases student obesity. The Physical Fitness Test (PFT), also called FitnessGram®, is given to students in grades 5, 7, and 9 each spring in California. Six fitness areas compose the PFT, one of which is body composition. Schools have the option

to complete the body composition portion using one of three measures: Body Mass Index (BMI), skin fold measurements, or bioelectric impedance analyzer. For each of these measurements, there is a defined “healthy zone” that varies by age and gender. The data are aggregated by school and grade level and indicate the percentage of students who have a body composition measurement in the healthy fitness zone. Following Currie et al. [2010], we define overweight as the percentage of students falling outside the healthy zone.

We do not find any evidence that contracting with a healthy lunch provider reduces the percentage of overweight students. We estimate Equation (1), except that we use the percentage of students who are outside the healthy fitness zone (whom we label as “overweight”) as the dependent variable and restrict the sample to grades 5, 7, and 9.²⁶ Columns (1) and (2) of Table 6 show estimation results for all students and economically disadvantaged students, respectively. On average, 38.6% of the students (41.7% of disadvantaged students) in our sample are overweight. All four point estimates in Columns (1) and (2) are small and statistically insignificant. However, a lack of precision prohibits us from excluding an effect size as large as that found by Currie et al. [2010] (5.2%) for all but one of the coefficient estimates (All Students, Healthy Vendor). One explanation for why we find no effect on the percent of overweight students is that both standard and healthy lunch providers faced the same USDA calorie requirements, even prior to the HHFKA (USDA 2012b). Fast-food restaurants, in comparison, face no constraints on calories.

²⁶The Contract School sample for this regression includes 4,006 grade-year observations at 910 schools.

5.2 Number of Lunches Served

The first provisions of the HHFKA became binding beginning with the 2012-13 school year. One criticism of the law is that improving the health content of lunches may have the unintended consequence of reducing the number of students eating school lunches (Confessore 2014), possibly because of students' tastes. A decrease in the number of meals served to students eligible for reduced price or free lunches would be concerning because these students are considered most at risk for undernourishment and are a target population of the NSLP.

In order to estimate the impact of vendor quality on the number of lunches served in a district, we obtained NSLP data from the California Department of Education's Nutrition Services Division for the school years 2008-09 through 2012-13. The data report the average number of total NSLP lunches and the average number of free, reduced-price, and paid lunches served per operating day in each school district for each month. We use the monthly averages to calculate a single operating day average for the total number of lunches served and the number of free or reduced-price lunches served over the course of the academic year.²⁷

Columns (3) and (4) of Table 6 report the impact of contracting with healthy and standard vendors on the number of daily lunches served per student. Column (3) estimates the effects on total lunches, while Column (4) estimates the effects on reduced price and/or free lunches. These regressions are run with observations at the level of district-year, rather than school-

²⁷We provide details of this calculation in Appendix A2.

grade-year, because data on lunch purchases is only available aggregated at the district level. This constraint imposes minimal cost, however, because the treatment only varies at the district-year level. The dependent variable is the number of daily lunches sold per student (in Column (4), we only consider the number of reduced price and/or free lunches and the number of economically disadvantaged students). We do not find a significant effect of contracting with a healthy or standard vendor on the total number of lunches or the number of free and reduced price lunches. For example, the estimated coefficients for contracting with a healthy or a standard vendor in Column (3) are of a similar magnitude and imply a statistically insignificant reduction in the number of school lunches of approximately 10% (the sample mean of the dependent variable is 0.45).

The fact that disadvantaged students do not purchase more school lunches when the school contracts with a vendor supports the interpretation that the observed increase in test scores is due to the quality and not the quantity of school lunch meals consumed. At the same time, these findings help allay concerns that healthier lunches may actually lead to a reduction in the number of lunches served to students and are consistent with recent evidence in Johnson et al. [2016] that the Healthy Hunger-Free Kids Act increased nutritional quality without affecting student meal participation rates.

The data on number of lunches served allow us to form a rough estimate of the effect of a school lunch on performance, or the “effect of the treatment on the treated” (TOT). If we view the treatment as exposure to a meal, rather than exposure to a vendor, the estimates in Tables 2 through 4 represent

“intent-to-treat” (ITT) effects since a significant fraction of students do not eat school meals. Column (3) of Table 6 reveals that, on average, schools serve 0.45 lunches per test taker.²⁸ Since vendors do not affect lunches sold, this figure suggests that the TOT estimate is approximately $1/0.45 = 2.2$ times the ITT estimate. The meals sold data are at the district level. Using a district-level regression result (Column (5) of Table 4) we find an ITT effect of 0.037 that translates to a TOT effect of 0.082. This effect is statistically significant at the $p < 0.01$ level.

5.3 Policy Counterfactual

Public school administrators interested in improving the level of student learning and increasing test scores face decisions on how best to budget limited school resources. There are many potential changes in school policy that could improve learning. For example, school administrators could hire more teachers to decrease average classroom size (Krueger 1999), lengthen the school day (Patall et al. 2010), increase teacher training (Angrist and Lavy 2001), give bonus pay to teachers based on student test scores (Fryer 2011), or increase student access to free or reduced price breakfast and lunch (Imberman and Kugler 2014).²⁹

Policies that direct resources toward teachers have been found to have a relatively large impact on student test scores in some settings. The Tennessee

²⁸This approximation should be reasonably accurate as long as there are not many students that eat school breakfast but bring their own lunches. This group seems likely to be small because lunch participation rates are much higher than breakfast participation rates; Dahl and Scholz [2011] estimate that the number of lunches delivered was 2.24 times greater than the number of breakfasts delivered in the most recent year in their data (2002-2003).

²⁹This list highlights only a handful of policies and is not meant to be exhaustive.

STAR experiment, which reduced average class size for primary school students by one-third and led to a 0.22 standard deviation test score increase, is a frequently cited benchmark. Nevertheless, these types of policies are often expensive and can be controversial (e.g., incentive pay). The Tennessee STAR experiment cost approximately \$25 million (2013 \$), with an implied cost of \$3,009 (2013 \$) per student placed in a smaller class.³⁰ Jacob and Rockoff [2011] highlight both the need and opportunity for cost-effective policies; lower-cost policies with modest effects on student test scores may generate a better return than costly policies with larger absolute effects.

We take advantage of contract-specific winner and loser bid information submitted to the CA Department of Education to calculate the cost of contracting with healthy lunch providers. The average price per lunch in healthy meal vendor contracts is \$2.60. Two comparisons suggest that healthy vendor pricing is competitive with other alternatives. First, in seven contracts that appear in our data involving 18 bidders, both healthy and standard vendors bid on the same contract. A regression of log price per test taker on a healthy vendor indicator and contract fixed effects reveals that healthy vendors bid 17.6% less than other vendors in these cases, and we can reject the hypothesis that healthy vendors cost at least 5.1% more than other vendors at the 95% confidence level.³¹ Second, the contract lunch price of \$2.60 is close to the National School Lunch Program reimbursement rate of \$2.93 per free lunch,

³⁰The original cost estimates reported by Krueger [1999] are adjusted to 2013 \$ using the Consumer Price Index (CPI).

³¹This regression compares healthy vendors to all other vendors, including those with unknown quality. Limiting the comparison to known standard vendors, however, generates similar results, with a cost difference of -22.8% and a 95% confidence interval that reaches 6.3%.

suggesting that healthy school meal vendors do not cost dramatically more than in-house preparation.

To compute a plausible upper bound on the cost of increasing test scores via healthy school meal vendors, we assume that healthy school meal vendors cost 25% more than in-house preparation. This assumption implies that the average school makes a net profit of 30% on its school meal operations when reimbursed by the NSLP. A profit margin of this size or larger is unlikely because the NSLP specifically forbids the use of these revenues to fund non-food service operations (GPO, 7 CFR, Section 210.14(a)).

The average healthy vendor meal contract is \$491 (2013 \$) per test-taker per school year. Over the 180-day academic year, a healthy school meal contract costs about \$2.73 per test-taker day (this figure is different than the \$2.60 meal cost because not every test taker eats a school meal, and some test takers eat both breakfast and lunch). We assume that the contract is 25% more expensive than in-house meal preparation, implying a difference of \$123 per test-taker per school year. To compare cost effectiveness we consider the dollar cost per 0.1 standard deviations of test score gains. This normalization does not imply that we can achieve a full 0.1 standard deviation increase with any given policy, including healthy vendor contracts (though the TOT estimate in Section 5.2 is close to 0.1). Rather, we recognize that policymakers have a menu of policies available for increasing test scores, and an optimizing policymaker will choose the combination of policies that yields a 0.1 standard deviation test score increase at the lowest possible cost.

Using a cost difference of \$123 per test-taker per school year and an es-

estimated effect of 0.031 standard deviations (Column (3) of Table 2), we find that it would cost about \$397 per year to raise a student's test score by 0.1 standard deviations through switching from in-house preparation to a healthy lunch provider. In contrast, it cost \$1,368 per year to raise a student's test score by 0.1 standard deviations in the Tennessee STAR experiment. Thus, even the upper bound on the cost of raising test scores by 0.1 standard deviations through healthy meals is several times lower than the comparable observed cost in Tennessee STAR.

6 Conclusion

We exploit variation in the nutritional quality of school meals resulting from changes in meal providers to estimate the effect of nutritional quality on the academic performance of primary and secondary school students across the state of California. Using difference-in-differences type specifications, we find that switching to a healthy meal vendor is associated with a 0.031 standard deviation increase in test scores. While this effect is modest in magnitude, the relatively low cost of healthy vendors when compared to in-house meal preparation makes this a very cost-effective way to raise test scores.

We conduct a variety of robustness checks, including placebo tests and an event-study specification, to provide evidence that the timing of changes in meal providers is uncorrelated with omitted variables that could be driving changes in test scores. There is also no evidence that the introduction of healthier school lunches led to a change in the number of school lunches

consumed. This supports our view that the observed relationship between healthier school lunches and test scores is due to the nutritional quality of the meals rather than the quantity of calories consumed. An analysis of the effects of healthy meal vendors on the percentage of students who are overweight finds no effect, but it is possible that these effects could materialize on a longer time horizon.

8 Figures and Tables

Figure 1: The Effect of Healthy Vendors on Test Scores

Notes: This figure depicts point estimates for treatment leads and lags with their corresponding 95% confidence intervals. Negative event time years are for years prior to having a vendor. Positive event time years are for years after the vendor contract begins (assuming that it continues). The point estimates come from a weighted regression of Equation (2) using the number of test-takers per observation as weights and can be interpreted relative to having no vendor and relative to the year before a vendor. The event time period -3 (3) is pooled to include both period -3 and -4 (3 and 4) to improve precision. The regression includes the same control variables as Table 2, Column (3). Standard errors are clustered at the school district level.

Figure 2: The Effect of Standard Vendors on Test Scores

Notes: This figure depicts point estimates for treatment leads and lags with their corresponding 95% confidence intervals. Negative event time years are for years prior to having a vendor. Positive event time years are for years after the vendor contract begins (assuming that it continues). The point estimates come from a weighted regression of Equation (2) using the number of test-takers per observation as weights and can be interpreted relative to having no vendor and relative to the year before a vendor. The event time period -3 (3) is pooled to include both period -3 and -4 (3 and 4) to improve precision. The regression includes the same control variables as Table 2, Column (3). Standard errors are clustered at the school district level.

Table 1: The Correlation between Test-Taker Covariates and the Timing of School Lunch Vendor Contracts

Dependent variable:	(1) White	(2) Asian	(3) Hispanic	(4) Disadvantaged	(5) English Learner	(6) Predicted Test Score
Panel A. All School Sample						
Healthy Vendor	0.004 (0.005)	-0.006 (0.004)	0.004 (0.003)	0.000 (0.015)	-0.016 (0.018)	0.005 (0.010)

Schools	7,607	7,607	7,607	940	940	940

Notes: Each column represents a separate weighted regression with weights equal to the number of test takers in the subgroup indicated by the column name. All regressions are estimated on a common sample that excludes observations with missing test score data for any of the indicated subgroups. Observations are at the school-grade-year level. Standard errors clustered at the school district level appear in parentheses. All regressions include year and school-by-grade fixed effects and district-level demographic covariates. * p < 0.05, ** p < 0.01, *** p < 0.001

Table 4: The Effect of Vendor Choice on Standardized Test Scores:
Robustness Checks

Dependent Variable:	Standardized Test Score					
	(1)	(2)	(3)	(4)	(5)	(6)
Model:	Nonconcurrent Effects	HEI Method 2	Continuous HEI	District-level Regression	Placebo	Standard Only
Healthy Vendor	0.031** (0.010)	0.036*** (0.009)		0.037** (0.013)	0.033** (0.012)	0.031 (0.028)
Standard Vendor	-0.004 (0.019)	-0.003 (0.016)		-0.010 (0.022)	-0.003 (0.019)	0.006 (0.021)
Healthy Vendor with Contract Ending Before Test Date	0.063** (0.018)					
Vendor with HEI Score			0.005 (0.014)			
HEI Score / 100			0.125* (0.060)			
Healthy Vendor Placebo					0.009 (0.011)	
Standard Vendor Placebo					0.012 (0.010)	
R ²	0.930	0.930	0.930	0.985	0.930	0.931
N	174,818	174,818	174,818	4,057	174,818	12,117
Schools/Districts	9,719	9,719	9,719	908	9,719	649

Notes: Each column represents a separate weighted regression with weights equal to the number of test takers per observation. In Column (1) the Healthy Vendor indicator equals zero when the Healthy Vendor with Contract Ending Before Test Date indicator equals unity. To construct the HEI Score regressor we subtract the mean standard vendor score (56) from HEI Score and rescale it by 1/100 (we also set the variable to zero for unscored vendors and schools with no vendors). Observations are at the school-grade-year level or, in Column (4), district-year level. Standard errors clustered at the school district level appear in parentheses. All regressions include year and school-by-grade (or, in Column (4), district) fixed effects and district-level demographic covariates. * p < 0.05, ** p < 0.01, *** p < 0.001

Table 5: The Effect of Vendor Choice on Standardized Test Scores:
Testing Alternative Explanations

Dependent Variable: Sample:	Standardized Test Score					
	School Expenditures		New Superintendent		Charter School Population	
	(1)	(2)	(3)	(4)	(5)	(6)
Healthy Vendor	0.028** (0.011)	0.028** (0.011)	0.031 (0.016)	0.031** (0.012)	0.031*** (0.010)	0.031*** (0.010)
Standard Vendor	-0.005 (0.019)	-0.004 (0.018)	-0.011 (0.014)	-0.011 (0.027)	-0.004 (0.019)	-0.004 (0.019)
Expenditures		0.001 (0.001)				
Student-Teacher Ratio		-0.001 (0.001)				
New Superintendent				0.002 (0.003)		
Percent Charter School Enrolled						-0.036 (0.062)
R ²	0.930	0.930	0.931	0.931	0.930	0.930
N	168,377	168,377	103,238	103,238	174,798	174,798
Schools	9,312	9,312	5,696	5,696	9,719	9,719

Each column represents a separate weighted regression with weights equal to the number of test takers per observation. Columns (1) and (2) estimate our model on a sub-sample of the panel with non-missing information for school expenditures and student-teacher ratio. Columns (3) and (4) estimate our model on a sub-sample with non-missing information on whether there was a new school district superintendent during our panel period. Columns (5) and (6) estimate our model on a subsample of schools with non-missing information on charter school enrollment. Observations are at the school-grade-year level. Standard errors clustered at the school district level appear in parentheses. All regressions include year and school-by-grade fixed effects and district-level demographic covariates. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Table 6: The Effect of Vendor Choice on Percent of Overweight Students and Number of School Lunches Sold

Dependent variable:	Body Mass Index		Number Lunches Sold	
	(1)	(2)	(3)	(4)
Subgroup:	All	Disadvantaged	All	Disadvantaged
Healthy Vendor	-0.32 (0.71)	0.14 (1.32)	-0.049 (0.037)	-0.078 (0.097)
Standard Vendor	-1.01 (0.84)	0.47 (1.48)	-0.035 (0.044)	-0.019 (0.119)
Dependent variable mean	38.58	41.67	0.447	0.418
R ²	0.831	0.764	0.760	0.721
N	43,648	18,105	2,778	2,744
Schools/Districts	8,724	8,724	785	785

Notes: Each column represents a separate weighted regression. The dependent variable in Columns (1) and (2) is the percentage of students who are overweight. Observations are at the school-grade-year level and the weights are equal to the number of physical fitness test takers. The dependent variable in Columns (3) and (4) is the number of school lunches sold. Observations are at the school district-year level and weights are the total student enrollment in the district. The first two regressions include school-by-grade fixed effects, while the latter two include district fixed effects. All regressions include year fixed effects and district-level covariates. Standard errors clustered at the school district level appear in parentheses. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

Appendix

Not For Print Publication

A1 Calculation of vendor HEI scores

Nutritionists at the Berkeley Nutrition Policy Institute conducted an analysis of menus for those vendors for whom this information was available. A copy of the complete report can be found here: <http://faculty.weatherhead.case.edu/jpg75/pdfs/Nutrition-Policy-Institute-July-2016.pdf> The menus were scored using the Healthy Eating Index (HEI). The process to calculate the HEI for each vendor was the following:

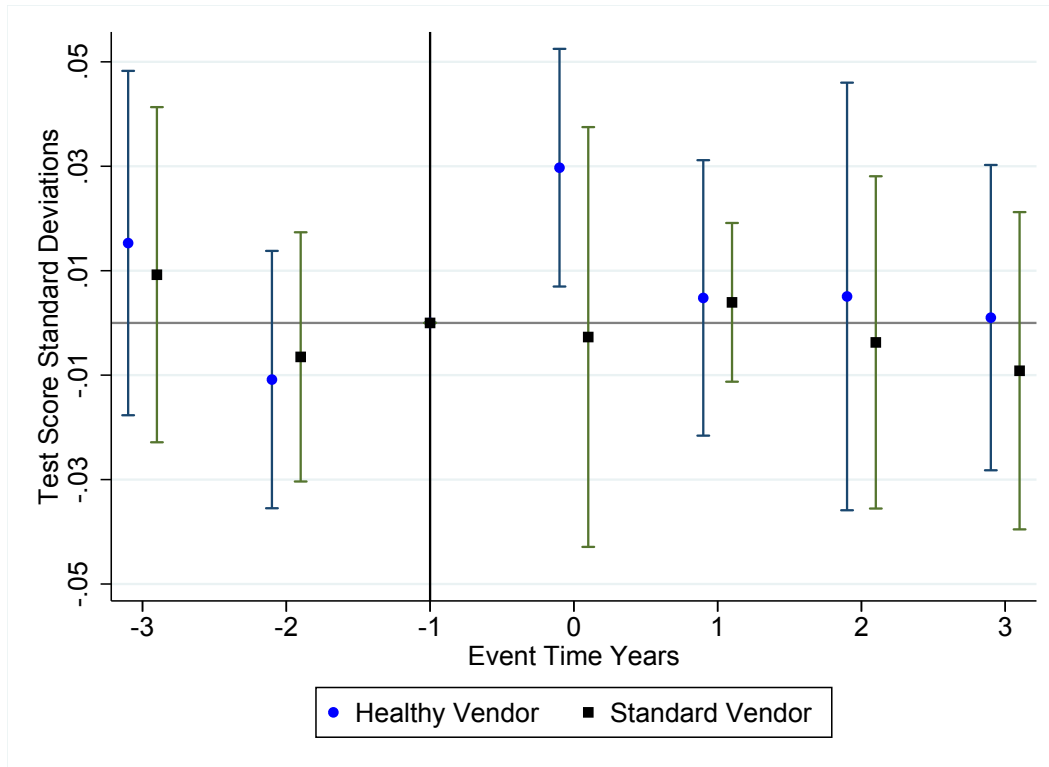

1. Nutrition information was gathered from vendors. This process included obtaining the full menu of offerings and nutritional information by contacting vendors. When this information was not available, sample menus from client school districts (with or without nutritional information) were used.
2. In order to calculate HEI, it was necessary to match foods listed in vendor menus to USDA food codes.
 - (a) For vendors with nutritional information available, vendor foods were matched to USDA foods using the What's in the Foods You Eat online search tool
 - Foods were first matched by names. Then, these matches were analyzed based on calories and fat content to determine how many USDA units corresponded to a vendor's portion.
 - Units were calculated so that calories, total fat, and saturated fat matched within 20% difference.
 - Entrees, meat/meat alternatives, and whole grain items were also matched by protein and fiber.
 - A coding system was created to denote the quality of the match.
 - (b) For vendors without nutritional information, the number of total calories and other nutrients had to be imputed to determine the number of USDA units corresponding to a vendor's portion. In these cases, a number of methods were tested, which included using the average calories for other vendors and USDA defaults (e.g., the necessary amounts to meet USDA guidelines)

- (c) USDA HEI SAS macros were used to determine HEI scores (scoring system 1)
- 3. A supplemental scoring system was created to include additional food categories commonly found in school lunch menus. This method was reviewed by five nutrition experts.
- 4. The HEI and supplemental scores were combined to calculate alternative total scores (scoring system 2).

A2 Calculation of average school lunches served

National School Lunch Program (NSLP) data were obtained from the California Department of Education’s Nutrition Services Division for the school years 2008-2009 through 2012-2013. The data report the average number of NSLP lunches served per operating day in each school district. Averages are calculated monthly, so in order to obtain an annual measure for the average number of lunches served per day, we multiply the monthly averages by the number of operating days in each month and sum the monthly totals. The months of June and July are excluded from the total because these months may correspond to summer lunch programs that are managed separately. The annual total is divided by the total number of operating days in the year, again excluding June and July, to calculate an annual average of lunches served per day. Lastly, we divide the number of lunches served per day by the total enrollment in the school district to eliminate changes in lunches served that are due only to changes in the number of enrolled students. Because we are interested in separately estimating the effect on economically disadvantaged students, we calculate averages for both total lunches served and free and reduced-price lunches. A student is eligible for a free school lunch if his family’s income is less than 130% of the poverty level, and a reduced-price lunch if her family’s income is between 130% and 185% of the poverty level. The CA Department of Education refers to these students as “economically disadvantaged.”

Figure A1: Placebo Test for the Effect of Contracting with a Vendor on Test Scores

Notes: This figure depicts point estimates for treatment leads and lags with their corresponding 95% confidence intervals. Negative event time years are for years prior to having a vendor. Positive event time years are for years after a vendor contract ends. The point estimates come from a weighted regression of Equation (2), except that the coefficients for $\tau > 0$ are redefined to be years after the end of a contract. The event time period -3 (3) is pooled to include both period -3 and -4 (3 and 4) to improve precision. The regression includes the same control variables as Table 2, Column (3). Standard errors are clustered at the school district level.

Notes: The table lists the 45 vendors that contracted with schools during the 2008-2009 to 2013-2014 school years. The Healthy Eating Index scores for each vendor are based on lunch menus and calculated by nutritionists at the Nutrition Policy Institute. The percent of students served by each vendor is determined by first summing the number of students in our panel that take the end of year academic (STAR) test who are in schools being served by an outside vendor for the test year, and then dividing this total by the number of students who have their meals provided by each vendor.

Table A2: Test-Taker Covariates for Schools that Contract with School Lunch Vendors

Sample:	All School Sample			Contract School Sample		
	(1) Vendor	(2) No Vendor	(3) Difference	(4) Healthy	(5) Standard	(6) Difference
